Explosion-proof valve of energy storage cabinet

Overview

Should deflagration venting be used as passive explosion protection?

In general, using deflagration venting as passive explosion protection in addition to an active system has multiple benefits due to the nature of the battery failure event, which involves a rapid release of flammable gases.

Why is a flammable vapor enclosure important?

In any situation where flammable vapors or combustible dusts are present, it is required to control or mitigate the risk of fire and explosions. The leading cause of fires and explosions inside these enclosures is an overheating battery leading to thermal runaway which leads to the release and ignition of combustible vapors.

How does ESS design affect fire and explosion safety?

Several competing design objectives for ESS can detrimentally affect fire and explosion safety, including the hot aisle/cold aisle layout for cooling efficiency, protection against water and dust ingress into the enclosure, and the use of larger cells with increased energy density.

Can passive protection be used as a sole explosion protection scheme?

The two main challenges in using passive protection methodology are design constraints for the enclosure and lack of validation data to support calculation methodology. These challenges make it difficult to obtain a feasible design for deflagration venting of ESS enclosures as the sole explosion protection scheme for most configurations.

What causes fire & explosion inside a Bess enclosure?

The leading cause of fire and explosion inside a BESS enclosures is the release and ignition of combustible vapors from an overheating battery.

Why is deflagration venting important for ESS enclosures?

For ESS enclosures, as demonstrated by the above example, battery gas mixtures that have greater than 30% hydrogen are difficult to protect with deflagration venting as the sole explosion protection measure due to the high laminar burning velocity.
